2021

DEPARTMENT OF
POLYMER
ENGINEERING

Definition

Elastomer: Polymers that are capable of min. 100% reversible elongation. Low load (a few MPa) results in large deformation, which goes off immediately upon unloading.

Rubber (uncured) – raw rubber material - uncured

Rubber mix – uncured raw rubber + additives, curatives, fillers, reinf.

Rubber (cured) – cross-linked rubber mix

Elastomer can be **cross-linked** (cured rubber) or **thermoplastic** (TPE)

TPE: physical cross-links, incompatible soft (low T_g)+hard (high T_g) segments

Natural rubber production: https://youtu.be/lUg7r7fu_eo

rubber
cis-1,4-polyisoprene

trans-1,4-polyisoprene

Gutta-Percha

Rubber forms an amorphous structure

Gutta-percha forms crystalline arrays

Definition

Natural rubber (NR): cis-1,4-polyisoprene dispersed in water -> latex

water is coagulated, smoke is used to preserve -> smoked rubber

Natural rubber compared to synthetic rubber:

- Lower hysteresis
- Higher heat dissipation
- Higher mechanical properties

Synthetic rubber (SR): polymerization process is used to produce

butadiene-rubber, styrene-butadiene-rubber etc

Natural rubber NR
Polyisoprene IR

Styrene-butadiene rubber SBR

Ethylene-propylene EPDM

Polychloroprene CR

Butyl rubber IIR

Nitrile rubber NBR

Chlorinated polyethylene CM

Polybutadiene BR

Rubber recipe

What does a rubber recipe contain?

- Uncured rubber
- Curatives
- Additives (antioxidant, flame retardant, colouring)
- Fillers/Reinforcement (carbon black, silica, sand, etc.)
- Plasticizers (processing aids, plasticizers, extenders): mineral oil, natural oil, synthetic plasticizers

Curatives:

- Sulphur (S)
- Peroxide
- Resin
- Activator (e.g. Zinc-oxide + stearic acid)
- Accelerators (e.g. Sulfenamides)
- Retarders

Raw materials

Raw material of rubbers: uncured rubbers:

- Natural rubber (NR)
- Synthetic rubbers (e.g. BR, IR, SBR, EPDM...)

Natural rubber NR
Polyisoprene IR

Styrene-butadiene rubber SBR

Uncured rubber:

- Linear thermoplastic polymer
- Amorphous or semi-crystalline
- T_g below RT
- Low modulus, high deformability
- Use of uncured rubber is limited (latex, impact additives)
- Main applications after curing (crosslinking) as (cured) rubber

Butyl rubber IIR

Nitrile rubber NBR

Ethylene-propylene EPDM

Polychloroprene CR

Chlorinated polyethylene CM

Polybutadiene BR

Chlorosulfonated polyethylene CSM

Silicone MQ

Raw materials

Fillers/reinforcement

- Carbon black (most important): increases tensile and tear strength, and wear resistance significantly. Active CB: small size (10-15 nm to few μm), so it has large specific surface (up to 2 000 m^2/g).
- Kaolin clays
- Calcium carbonate
- Silica

Fillers' properties affect the properties as follows:

- With increasing specific surface, viscosity, tensile and tear strength, and wear resistance, hysteresis increase.
- With increasing surface activity, wear resistance, modulus and hysteresis increases.

A rubber recipe usually contains 10-15 components (proper design is necessary) which have to be distributed/dispersed homogeneously in rubber matrix.

Rubber mixing

Internal mixers - Banbury-type mixers

Friction between the rotors

Francis Shaw Intermix rotors

Farrel Bridge Banbury rotor

Rubber mixing

Mixing stages:

1. viscosity reduction
2. incorporation
3. distributive mixing
4. dispersive mixing

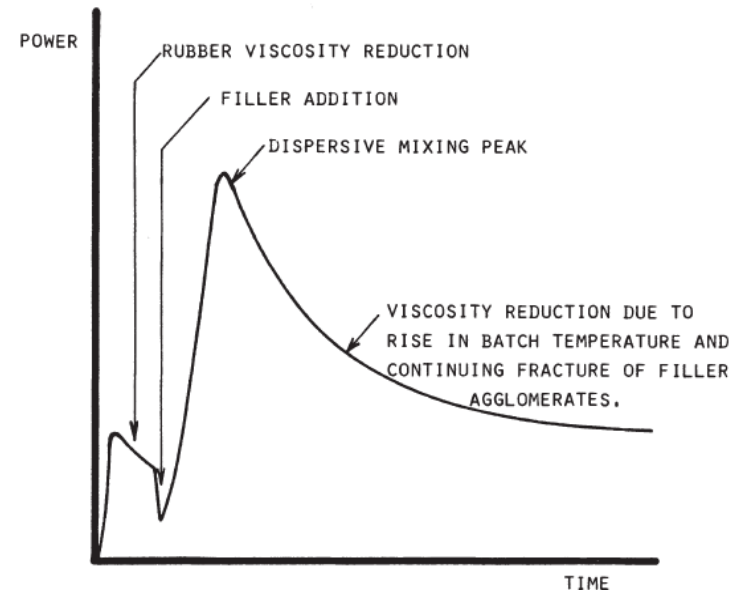

1. Temperature rise, chain extension, mastification (chain scission)
2. Low viscosity material flows around additives
3. Simultaneously with incorporation the volume of additives decreases
Folding flow+separation and recombination -> exponential mixing
4. Slow viscosity increase causes dispersive mixing

Rubber mixing

s^2 the variance of the maximum curemeter torque, n is the number of samples taken from a batch mixed to a specified value of the dump criterion, X_i is the value of the i -th sample, and \bar{x} is the average value of n samples, for a number of batches mixed to different dump-criterion values

$$s^2 = \frac{1}{n-1} \sum_{i=1}^n (x_i - \bar{x})^2$$

Rubber mixing

Internal mixers – laboratory scale

Rubber mixing

Rubber mixing: Roll mill/open mill

<https://youtu.be/7Ju7J9zJ1Ow>

Rubber mixing

Roll mill – laboratory scale

Rubber mixing

Roll mill

Shaping

Solution

Petrol was used before to dissolve caoutchouc

Nowadays watersolution is preferred -> latex

Before dissolving roll-mill is used to produce 3 mm thick plates

Impregnation

Textile is impregnated with low viscosity solution

Max 15 m% rubber is applied on the textile -> calendering or lubrication

Lubrication

It is only used for thin, impregnated textiles

Higher m% of rubber can be achieved than in the case of calendering

Lubrication knife is used disperse the rubber solution, dissolvent is evaporated

Shaping

Calendering for sheeting, coating

Lower temperatures compared to thermoplastic materials -> higher forces acting on the rolls

Feeding can be done by 2-3 internal mixers or extruder

Sheets: 3-4 calenders in a row

textile or PE foil is just for windig

0.1-2 mm thick sheets in one layer

above 2 mm thickness two layers are pressed together

Coating: one or two sided

two sided coating can only be done in one step with a 4 roll calender

steel and fabric is used mostly

Shaping

Extrusion - warm feed extruders

Simple screw design,
two or single start

Relies on the roll-mill for temperature control
Used when short runs and versatility needed
3-5D screw length
Conveying and pressurizing

Dump/batch extruder
Specil hot feed extruder
Designed to accept discharged mix from internal mixer
Large diameter screw plus pneumatic pusher
Slab or sheet

Shaping

Extrusion - cold feed extruders

New screw design

longer screw, decreased pitch, decreased flight depth -> longer residence time, better mixing, better heat transfer

Mixing screws and sections -> limited range of rubbers can be used efficiently

No roll-mill needed

Used when long runs and limited mixes

Advantages: lower capital cost
reduced labor cost
better temperature control
better dimensional control

- | | |
|---------------------|-------------------------|
| 1 Drive unit | 5 Pin barrel |
| 2 Gear unit | 6 Screw |
| 3 Feed zone | 7 Injection head |
| 8 Feed roll | |

Shaping

Extrusion – Pin/QSM extruder

Extrusion – Cavity transfer mixer

Hemispherical cavities

Flow stream division+reorientation

Exponential distributive mixing

Shaping

Shaping

Compression, transfer moulding

Rubber needs to be preheated -> microwave heater

Improved dimensional accuracy.

New and clean surfaces are generated on the rubber, which is extremely important for achieving a strong and consistent rubber-metal bond.

Transfer presses, lower unit manufacturing costs are possible.

Shaping

Injection moulding – typically with FiFo system

Compared to compression molding:

Better heat control

Higher temperature and flow rate -> reduced injection time and curing

Smaller runner system -> less waste

Shaping

Injection moulding –FiLo system

F.I.L.O. INJECTION SYSTEM

Shaping

Injection moulded products

Shaping

Injection moulded products

Curing

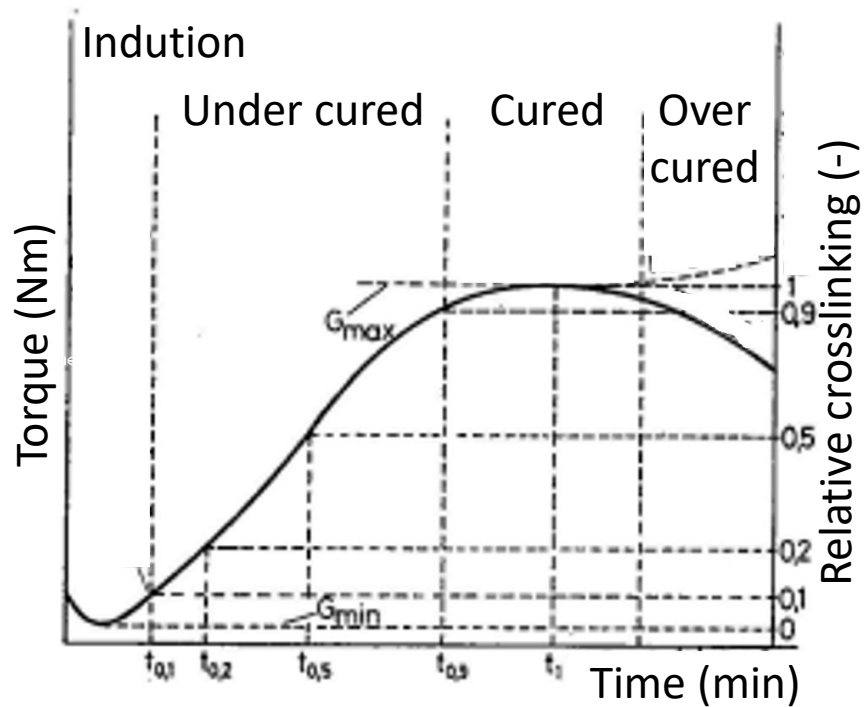

Curing: crosslinking process of rubber mixes

Sulfur for materials with double bonds

Peroxide for all others

Curing curve

$t_{0,1}$: scorch time, material starts curing, can't be formed anymore

$t_{0,9}$: optimal curing time

Post curing: reversion – decomposition of macro molecules rubber get softer
 post curing- rubber gets harder

Curing is influenced by: chemical factors – accelerators, activators, retargents etc.
 physical factors – pressure, time, temperature, moisture

Vulcameter

Curing processes

Discontinuous/batch

Autoclave: pressurized/vacuum cabin which is heated by gases/steam/hot air

Pressure furnace

Used for tyres

The mold is in the furnace, compression molding is done under pressurized steam

Continuous

Mostly for extruded parts: tubes, sheets, cables etc.

Can be done under pressure or without pressure

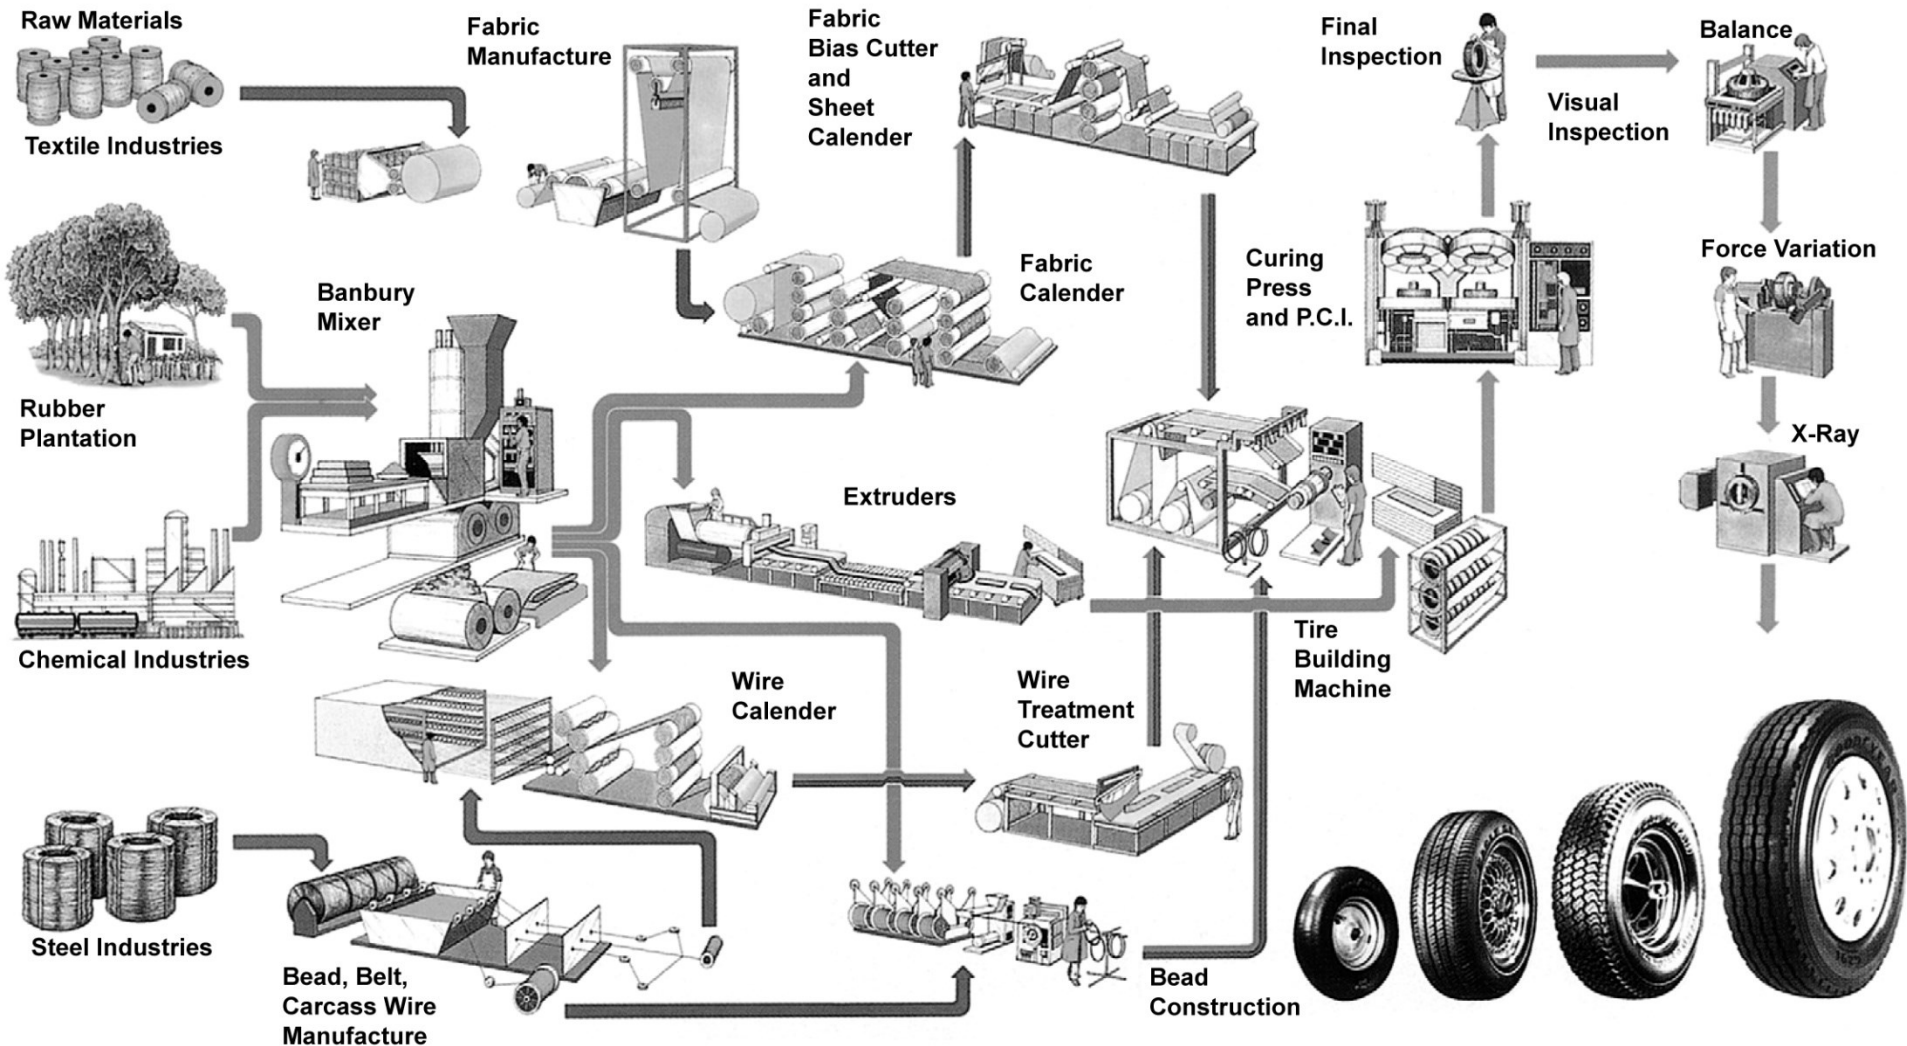

Tyre manufacturing

Tyre: complex rubber-based system

<https://youtu.be/Li-MKobBg5w>

Tyre manufacturing

Recycling

Recycling possibilities of rubbers:

- Devulcanization/regeneration
- Grinding of the rubbers (tyres, conveyor belts) and incorporating into:
 - Thermoplastic polymers
 - Rubber mixes
 - Asphalts
- Energy recovery
- Etc.
